

Hierarchical Search for Parsing

Adam Pauls and Dan Klein

Motivation

- Modern parsers users very large grammars (millions of rules!)
- Coarse-to-Fine has proven successful (Charniak and Caraballo 1998)
- Multi-level or Hierarchical Coarse-to-Fine works even better (Charniak and Johnson 2005, Petrov and Klein 2007)
- In this talk, we explore an optimal hierarchical search method: *Hierarchical A**

Hierarchical A*

(Felzenswalb and McAllester 2007)

- Basic Idea:
 - build both inside and outside edges as needed using same agenda
 - use coarse outside scores as heuristics for fine inside edges

Hierarchically Building Inside Edges

Coarse-to-Fine

- Prune edges in fine grammar based on posteriors from coarse grammar

Coarse-to-Fine

- Prune edges in fine grammar based on posteriors from coarse grammar
- We use Viterbi posteriors for pruning (Petrov and Klein 2007)

Coarse-to-Fine

- Prune edges in fine grammar based on posteriors from coarse grammar
- We use Viterbi posteriors for pruning (Petrov and Klein 2007)

$$\beta'(e) + \alpha'(e) \leq \text{threshold}$$

Agenda-Based CTF

- (Hierarchical) CTF can also be thought of as an instance of agenda-based parsing with

$$priority(e) = \begin{cases} \beta(e) & \beta'(e) + \alpha'(e) \leq \text{threshold} \\ \infty & \text{otherwise} \end{cases}$$

Agenda-Based CTF

- (Hierarchical) CTF can also be thought of as an instance of agenda-based parsing with

$$priority(e) = \begin{cases} \beta(e) & \beta'(e) + \alpha'(e) \leq \text{threshold} \\ \infty & \text{otherwise} \end{cases}$$

- This reformulation makes architectures directly comparable

One-Level CTF vs. A*

- Only one coarse grammar (the 3-split)
- CTF is faster than A*, but makes search errors

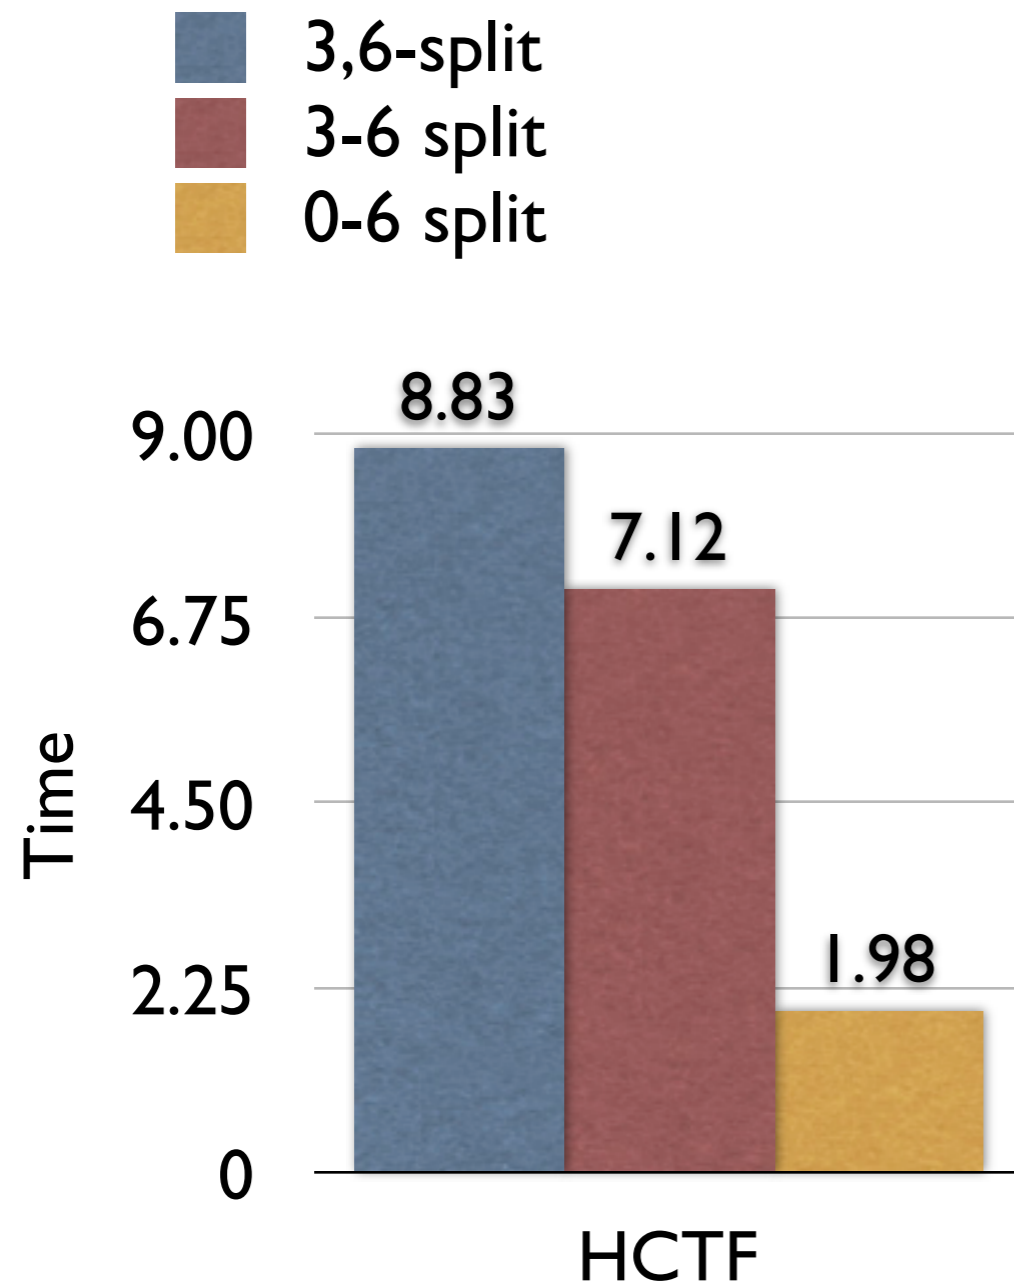

Hierarchies

- How do HCTF and HA^* scale with size of hierarchy?

Hierarchies

- How do HCTF and HA* scale with size of hierarchy?

Hierarchies

- How do HCTF and HA* scale with size of hierarchy?

Why A*?

- CTF is faster, and extends to hierarchies nicely, so why A*?
 - I. If you really don't want to make search errors

Cost of Optimality: State-Split Grammars

HCTF Speed vs. Search Errors

HCTF Speed vs. Search Errors

Cost of Optimality: State-Split Grammars

HCTF Speed vs. Search Errors

Why A*?

- CTF is faster, and extends to hierarchies nicely, so why A*?
 1. If you really don't want to make search errors
 2. For some problems, we can find very efficient, tight heuristics
 - In this case, A* is very fast

Experimental Setup #2

- We use the factored lexicalized grammar of Klein and Manning (2003)
- They construct a lexicalized grammar as the cross-product of a dependency grammar and PCFG

Cost of Optimality: Lexicalized Grammar

CTF Speed vs. Optimality

Conclusions

- Coarse-to-Fine is much faster for reasonable number of search errors
- Hierarchical Coarse-to-Fine effectively exploits multilevel hierarchies, Hierarchical A^* does not
- Hierarchical A^* is the right choice if
 - optimality is desired
 - heuristics are very tight

Thank you
